PRECURSORS OF ENGINEERED POWDERS

Related Applications.

The present invention claims priority to U.S. Provisional Application No. 60/267,653 Filed on February 12, 2001 entitled "ORGANOMETALLICS AND NANO-ENGINEERED POWDERS", the specification of which is incorporated herein by reference in its entirety.

BACKGROUND OF THE INVENTION

Field of the Invention.

The present invention relates, in general, to precursors useful in making fine powders, and, more particularly, methods to produce precursors, particularly organometallic precursors, and fine powders.

Relevant Background.

Powders are used in numerous applications. They are the building blocks of electronic, telecommunication, electrical, magnetic, structural, optical, biomedical, chemical, thermal, and consumer goods. On-going market demands for smaller, faster, superior and more portable products have demanded miniaturization of numerous This, in turn, demands miniaturization of the devices. building blocks, i.e. the powders. Sub-micron and nanoengineered (or nanoscale, nanosize, ultrafine) powders, with a size 10 to 100 times smaller than conventional improvement micron size powders, enable quality differentiation of product characteristics at currently unachievable by commercially available micronsized powders.

15

20

25

30

Nanopowders in particular and sub-micron powders materials novel family of whose general are distinguishing feature is that their domain size is so small that size confinement effects become a significant determinant materials' performance. of the confinement effects can, therefore, lead to a wide range properties. Nanopowders, commercially important therefore, are an extraordinary opportunity for design, development and commercialization of a wide range of products for various applications. devices and Furthermore, since they represent a whole new family of precursors where conventional coarse-grain material applicable, physiochemical mechanisms are not materials offer unique combination of properties that can enable novel and multifunctional components of unmatched Yadav et al. in a co-pending and commonly performance. assigned US Patent Application No. 09/638,977 which along the references contained therein are hereby incorporated by reference in full, teach some applications of sub-micron and nanoscale powders.

Some of the greatest challenges in the cost-effective production of powders involve controlling the size of the powders as well as controlling the composition of the powder. Precursor properties are significant contributors to these powder characteristics.

Precursors for nano-engineered powders are needed to quality nanomaterials costmanufacture superior in volume. Precursors significantly effectively and impact the economics of a process and quality of products A number of different high temperature processes formed. based on different precursors have been proposed for the For example, US Patent synthesis of nanoscale powders. 5,514,349 (incorporated by reference herein), teaches the

15

30

use of solid conducting electrode precursors to produce metal and ceramic powders. One difficulty with this approach is the cost and conductivity of the electrode. Furthermore, this process limits the ability to produce complex compositions because the composition of the product is directly dependent on the composition of the electrode. A wide variety of solid precursor electrodes are not readily available, and many desirable products do not have any corresponding electrode.

As another example, it is known to those in the art that halides such as titanium chlorides and gaseous metal-containing precursors such as diethyl aluminum and silane are precursors for powder production. These precursors can be used as precursors for high temperature processes to produce submicron and nanoscale powders. Similarly, US Patent 5,876,683 (incorporated herein) teaches the use of these and similar gaseous precursors to produce nanoscale powders.

These precursors create the challenge of postbyproducts such as chlorine, which 20 treatment of increase process complexity and cost. The product quality contamination. suffer because of chloride Another limitation is that processing equipment must be handle the corrosive intermediates configured to byproducts, hence, the processing equipment tends to be 25 expensive, require more frequent maintenance, and/or have short useful lifetimes.

Yet another limitation of such processes is the hazard and operability of the system as these precursors can undergo spontaneous reaction with other species involved in the process. Similarly, because many species spontaneously react with air or water, vapor which may be

10

15

20

25

30

involved in the manufacturing process or simply present in the manufacturing facility, handling and use becomes both problematic and expensive. Finally, another limitation of these high temperature processes is the general need to gasify the feed before it is added to oxygen, which requires additional processing equipment, additional cost, and creates more opportunity for variability and contamination in the production process.

Another approach to precursor selection has been to weight chelate-type polymeric use high molecular 5,958,361 herein (e.q. see U.S. Patent precursors incorporated by reference in full). These precursors have also been used in a high temperature process to produce complex oxide powders. However, and precursors are expensive to produce and have secondary The nitrogen or halides in these precursors byproducts. or their equivalent face many of the same challenges as The high molecular weight correlates with to high viscosity which can affect the size distribution of the powder produced.

Other approaches involve feeding solid powders into a high temperature process in order to break them down to In these approaches it may be difficult to smaller sizes. control size distribution and significant agglomeration of Moreover, the variety of powders that can the particles. by the availability produced is constrained To the extent the larger appropriate starting powders. similar produced by starting powders are described above, this technique incorporates many of the limitations described above as well.

In general, processes available until now are limited by the choice of the precursor they utilize. There is a

15

20

25

need for a process that utilizes low-cost, readily available precursors to produce high quality nanoscale powders. Moreover, there remains a need for precursors for powder production that are environmentally benign and require minimal pre-processing costs in high volume.

SUMMARY OF THE INVENTION

Briefly stated, the present invention involves the production and selection of precursors used to produce fine powders of oxides, carbides, nitrides, borides, chalcogenides, metals, and alloys. Methods for making powders using the selected precursor fine selecting a precursor mixture wherein the mixture comprises at least one metal containing precursor, the metal containing precursor has an average molecular weight of less than 2000 q/mol of the metal, the metal containing precursor has a normal boiling point greater than 350K, and the viscosity of the precursor mixture is between 0.1 250 cP. The precursor mixture is processed under conditions that produce the fine powder from the precursor mixture. Fine powders produced are of size less than 100 microns, preferably less than 10 micron, more preferably less than 1 micron, and most preferably less than 100 Methods for producing such precursors and nanometers. powders in high volume, low-cost, and reproducible quality are described.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 2 shows an exemplary overall approach for producing fine powders in accordance with the present invention; and

Fig. 3 shows a schematic flow diagram of a process for the continuous synthesis of precursors and nanoscale powders in accordance with the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

This invention is generally directed to very fine carbides, oxides, nitrides, powders of chalcogenides, metals, and alloys. of the The scope Fine powders teachings include high purity powders. discussed are of size less than 100 microns, preferably less than 10 micron, more preferably less than 1 micron, and most preferably less than 100 nanometers. Methods for producing such powders in high volume, low-cost, and reproducible quality are also outlined.

Definitions

For purposes of clarity the following definitions are provided to aid understanding of description and specific examples provided herein:

"Fine powders", as the term used herein, are powders that simultaneously satisfy the following:

- 1. particles with mean size less than 100 microns, preferably less than 10 microns, and
- particles with aspect ratio between 1 and
 1,000,000.

"Submicron powders", as the term used herein, are fine powders that simultaneously satisfy the following:

15

20

30

- 1. particles with mean size less than 1 micron, and
- 2. particles with aspect ratio between 1 and 1,000,000.

"Nanopowders" (or "nanosize powders" or "nanoscale powders"), as the term used herein, are fine powders that simultaneously satisfy the following:

- 1. particles with mean size less than 250 nanometers, preferably less than 100 nanometers, and
- particles with aspect ratio between 1 and
 1,000,000.

"Pure powders," as the term used herein, are powders that have composition purity of at least 99.9%, preferably 99.99% by metal basis.

"Precursor," as the term used herein encompasses any raw substance, preferably in a liquid form, that can be different of same transformed into a powder orThe term includes but is not limited to composition. organics, inorganics, solutions organometallics, organometallics, dispersions, sols, qels, containing emulsions, or mixtures.

"Organometallic," as the term used herein is any organic substance that contains at least one metal or semi-metal.

"Powder", as the term used herein encompasses oxides, carbides, nitrides, chalcogenides, metals, alloys, and combinations thereof. The term includes hollow, dense, porous, semi-porous, coated, uncoated, layered, laminated, simple, complex, dendritic, inorganic, organic, elemental, non-elemental, composite, doped, undoped, spherical, non-

10

15

20

spherical, surface functionalized, surface non-functionalized, stoichiometric, and non-stoichiometric form or substance.

This invention is specifically directed to precursor mixtures for forming fine powders, including submicron and sense, the invention In generic nanoscale powders. teaches a precursor mixture for forming submicron and nanoscale powders comprising (a) at least one metal containing species, (b) an average heat of combustion greater than 1 KJ/liter, preferably greater than KJ/liter, (c) a viscosity at 298 K between 0.1 cP and 250 cP, preferably between 0.25 cP and 100 cP, (d) a stability greater than 5 seconds, (e) the said metal containing species has a molecular weight less than 2000 g/mol, preferably less than 500 g/mol, (f) a normal boiling point (at 1 atmosphere) greater than 350K, preferably greater than 375K, and (g) where the metal concentration in the said precursor solution is greater than 5.5% by weight, preferably greater than 22% by weight. This precursor mixture may further comprise additives such as but not limiting to water, naphtha, toluene, benzene, hexane, acetic acid, oxalic acid, kerosene, gasoline, methanol, isopropyl alcohol, glycerol, polyol, and ethanol, petrochemicals.

Fig. 1 shows an exemplary overall approach for the 25 production of precursors mixtures or solutions. This method is particularly useful for producing organometallic precursors for sub-micron and nanoscale powders. The process shown in FIG. 1 begins with a metal containing raw material (for example but not limiting to coarse oxide 30 powders, metal powders, salts, slurries, waste product, inorganic compound). ororganic compound invention, a raw material is preferred using the following

10

15

20

25

30

criterion - cost is low per unit metal basis, high stability, environmentally and ecologically benign, and available in high volumes. The metal containing raw material is dissolved in a suitable solvent such as an acid. The concentration of the dissolved solution is preferably monitored to ensure that concentration is within desired parameters for a particular implementation.

preferred embodiment, the dissolution In results in a dilute solution. If required, the dissolved solution is diluted with demineralized water (or any other suitable solvent) to concentrations less than 0.25 mols per liter, preferably less than 0.025 mols per liter, and most preferably less than 0.0025 mols per liter. embodiment, dopants may be added at this stage to produce complex organometallics. In another embodiment, other solutions of dilute metal containing dissolved solutions The temperature added at this stage. dissolution media is preferably selected to balance or optimize the acceleration of the dissolution step while minimizing the energy costs.

dissolved solution is then treated with to form а metal containing precipitating agent It is preferred that the precipitating agent precipitate. be added slowly to the dissolved solution. Alternatively, it is preferred that the precipitating agent is dilute. The temperature of the solution is preferably controlled precipitate characteristics. Lower optimize the temperatures reduce the reaction and diffusion rates. An important goal of this step is that the diffusion rate of reactants at the precipitation interfaces is slower than the mixing rate of the precipitates in the solution bulk, preferably less by a factor of 2.5. This addition step may occur in a continuously stirred mixed tank reactor or

10

15

20

25

30

in a plug flow reactor or in any equipment that enables the control of precipitation and mixing rates.

For example, in one embodiment, if the pH of the dissolved solution is less than 7.0, ammonium hydroxide may be added to form the metal containing hydroxide precipitate. This precipitates a hydroxide from the dissolved solution.

The precipitate formed is filtered using a filter press. In another embodiment, the precipitate containing solution is centrifuged to remove the solids from the liquids. In yet another embodiment, the precipitate is settled using gravity and then decanted. Any other method of solid liquid separation may be utilized at this stage to obtain the filtered precipitate.

The filtered precipitate is washed with demineralized water or any other suitable solvent or solvent combinations as many times as desired. The objective at this stage is to remove any acid, dissolved solution, or alkali from the precipitate surface. It is preferred if the extent of washing needed is monitored by a suitable instrument such as a pH meter.

The washed precipitate is then added to a solvating or complexing agent. This agent is preferably chosen for its ability to react with the precipitate to produce an organometallic fluid. The addition step may be performed in a stirred tank reactor or a plug flow reactor or any other suitable reactor. The organometallic precursor may be removed as it is formed to accelerate the solvation step. If the precipitate is mixed in the reactor, the mixing can be achieved using a stirrer, sparging system, solvating agent recycle system, jet mixing, and other methods. The temperature of the mixing step may be

10

15

20

25

controlled to accelerate the synthesis step or to avoid secondary reactions. Suitable catalysts may be employed at this stage.

As a non-limiting example, 2 ethylhexanoate may be used as this solvent reacts with the hydroxide functional group and produces an organometallic. Other illustrations can utilize any suitable organic acid capable of reacting with the hydroxide precipitate. This step yields an organometallic precursor.

precursor mixture can be produced using reaction pathway and using any process equipment However, the scope of this invention is instrumentation. precursors useful to the production limited to nanoscale or submicron nanoparticles. These precursors can be used in any method for producing nanoscale or fine Illustrative methods include commonly-owned powders. issued U.S. patents 5788738, 5851507, 5984997, and copending applications 09/638,977 and 60/310,967, which along with references therein are incorporated herewith in full.

The precursor may be a mixture. It is preferred that the mixture be homogeneous and that this precursor mixture be stable, i.e., homogeneity remains acceptable for a duration greater than the feed residence time in the process it is being used. As a rule of thumb, a stability greater than 5 seconds is preferred, a stability greater than 5 minutes is more preferred, and a stability greater than 5 hours is most preferred.

The precursor solutions (or mixtures) within the scope of the invention preferably have an exothermic heat of reaction with oxygen or oxygen containing feed gases. It is preferred that the precursor solution should

15

20

25

30

generate enough thermal energy during its chemical reaction with oxygen or oxygen containing feed gases that it can lead to a self-sustained chemical reaction at an average temperature above the boiling point (at 0.1 atmospheres) of lowest boiling species in the precursor mixture. More specifically, the heat released during the precursor mixture's reaction with oxygen is on average greater than 1 kJ per liter of the precursor mixture, preferably greater than 10 kJ/liter, more preferably greater than 25 kJ/liter, and most preferably 75 kJ/liter.

The precursor solutions (or mixtures) within the scope of the invention have low vapor pressures at 298 K. More specifically, the normal boiling point of the metal containing precursor (i.e., at 1 atmosphere) is on average greater than 350K, preferably greater than 375K, more preferably greater than 400K, and most preferably 425K.

The precursor solutions (or mixtures) within the scope of this invention have a viscosity that makes them easy to feed. More specifically, the viscosity of the precursor mixture at 298K is on average between 0.1 to 250 cP, preferably between 0.25 to 150 cP, more preferably between 0.5 to 100 cP, and most preferably between 0.75 to 75 cP. The viscosity is established in a range such that the precursor mixtures are neither gas, nor solid.

The precursor solutions (or mixtures) within the scope of the invention have high metal concentration by weight for high production rates and productivity. More specifically, the metal content in the precursor mixture is greater than 5.5 weight percent, preferably greater than 11 weight percent, more preferably greater than 22 weight percent, and most preferably greater than 33 weight percent.

15

20

25

30

To further particularly define the invention, the precursor solutions (or mixtures) within the scope of the invention comprise at least one metal containing species. More specifically, the average molecular weight of the metal precursor per unit mol of metal (or metals) in the precursor is less than 2000 g/mol, preferably less than 1000 g/mol, more preferably less than 800 g/mol, and most preferably less than 600 g/mol. In some embodiments, where the mols of metal in the precursor are not readily determinable, this invention prefers an average molecular weight of the metal precursor, comprising at least one less than 2500 g/mol, preferably less than 1500 metal, g/mol, more preferably less than 1000 g/mol, and most preferably less than 750 g/mol. In some embodiments, the metal containing precursor molecule may comprise of more than one metal in its molecular structure. In such cases, it is preferred that the precursor have less than or equal to six same metallic elements, more preferably less than equal to four same metallic elements, and preferably less than or equal to two same elements in its molecular structure.

Depending on the end use of the organometallic precursor, other treatments may be performed on the precursor. To illustrate, but not limit, a precursor with characteristics outlined above can be mixed with other precursors with similar characteristics to produce complex multi-metal compositions. Alternatively, solvents such as but not limiting to alcohols, acids, hydrocarbons, or oils may be added to dilute the concentration or to change the viscosity or density of the organometallic precursor. Additionally, stabilizing agents may be added to increase the storage and shelf lifetime for the organometallic precursor.

15

20

25

30

The precursors with preferred embodiments discussed above may be processed into powders by, for example, reacting the precursor with oxygen or a gas comprising oxygen to form oxides, nitrogen, ammonia orqas comprising nitrogen to form nitride, methane or gas comprising carbon to form carbide, borane or gas comprising boron to form boride, hydrogen or gas comprising a reducing gas to form metal or suboxides. Other inorganic nanoparticles may similarly be formed by reacting the precursors with suitable gases.

Figure 2 shows an exemplary overall approach for the production of fine powders in general and nanopowders in The process shown in FIG. 2 begins with a particular. metal containing raw material (for example but limiting to coarse oxide powders, metal powders, salts, slurries, waste product, organic compound or inorganic The metal containing raw material is dissolved in a suitable solvent such as an acid (e.g. nitric acid). The concentration of the dissolved solution is checked to ensure that it is not too concentrated. In a preferred embodiment, the dissolution step results in a dilute solution. If required, the dissolved solution is diluted with demineralized water (or any other suitable solvent) to concentrations less than 0.5 mols per liter, preferably less than 0.05 mols per liter, and most preferably less than 0.005 mols per liter. For smaller particle sizes, lower concentration is normally preferred. However, higher concentrations are preferred when higher saturation is desired or when energy costs are to be lowered.

The solvent composition for dissolution is chosen that reduces the diffusion rate of reacting species in the solution (for example, alcohols such as ethanol may be

added to water to tailor the mass transfer and momentum transfer characteristics of the solution). In embodiment, dopants may be added at this stage to produce In another embodiment, complex nanopowders. solutions of dilute metal containing dissolved solutions this The temperature may be added at stage. is optimized in one embodiment dissolution media dissolution step while minimizing the accelerate the energy costs.

dissolved solution is The then treated with 10 precipitating agent to form a metal containing precipitate (i.e., a sol). It is preferred that the precipitating agent be added slowly to a large volume of the dissolved solution (the ratio of the large volume to small volume In another embodiment, it is being greater than 2). 15 preferred that the precipitating agent be dilute. concentration of the precipitating agent should be higher than that required thermodynamically for the precipitate to form.

In another embodiment, the dissolved solution is added slowly to a large volume of the precipitating agent (the ratio of the large volume to small volume being greater than 2). This is particularly useful when a homogeneous multi-metal precipitate is desired. Once again, the concentration of the precipitating agent should be higher than that required thermodynamically for the precipitate to form.

The temperature of the solution is preferably controlled to optimize the precipitation characteristics. Lower temperatures reduce the reaction and diffusion rates. The key aspect of this step is that the diffusion rate of reactants at the precipitation interfaces be

30

15

25

slower than the dispersion rate of the precipitates in the solution bulk, preferably less by a factor of 2.5. preferred if the solution concentrations and processing conditions are varied to decrease the precipitate growth rate while increasing the precipitate nucleation rate. It is also preferred if the processing parameters are varied using an on-line instrument that monitors the precipitate size distribution (e.g. laser scattering). This addition step may occur in a continuously stirred mixed tank reactor or in a plug flow reactor or in any equipment that enables the control of precipitation and mixing rates. eductor, that is a venturi system, is preferred for the mixing of dissolved solution and the precipitating agent solution. One of the solutions is fed at high pressure to the converging section of the venturi system. The flow causes a low pressure to develop in the throat of the venturi which is utilized to introduce the other solution at the throat. The mixed product then exits the diverging section of the venturi.

In another embodiment, it is preferred that a plug flow system be used. A plug flow eliminates axial mixing and thereby can yield narrow size distribution nanopowders (monosize powders). The design principle preferred for the design of plug flow reactor system is given by:

 $UL/D > \beta$

Where,

U: axial velocity

L: axial length of the reactor

D: axial dispersion coefficient

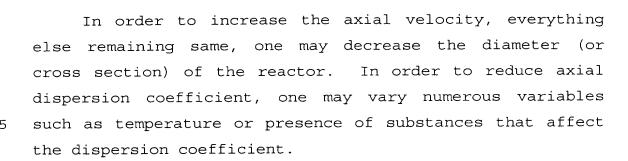

30 β : plug flow index (preferably equals 5, more preferably equals 50, and most preferably equals 500)

15

20

25

30

Illustrations of precipitating agent include ammonium hydroxide, ammonia, alkalis, hydrogen peroxide, and weak bases to form the metal containing hydroxide precipitate. This precipitates a hydroxide from the dissolved solution. Alternatively, gas-liquid reaction apparatus may be utilized to react a gas phase precipitating agent (for example, ammonia vapors). In yet another embodiment, electrical current or electromagnetic fields or photons may be utilized to facilitate or optimize precipitation.

The precipitate formed is filtered using a filter press assisted with or without vacuum. In another embodiment, the precipitate containing solution is centrifuged to remove the solids from the liquids. In yet another embodiment, the precipitate is settled using gravity and then decanted. Any other method of solid liquid separation may be utilized at this stage to separate the filtered precipitate.

The separated filtered precipitate is washed with demineralized water or any other suitable solvent or combinations thereof as many times as necessary. The objective at this stage is to remove any acid, dissolved solution, undesired co-precipitated salts or alkali from the precipitate surface. The preferred solvent would reduce agglomeration and remove the liquid without further precipitation of any solid between the precipitate particles. Illustration of such solvents include those

10

15

20

25

30

that have low surface tension (e.g. alcohols, ketones, aliphatic solvents, mixtures). aldehydes, aromatics, During the washing step, mixing or milling may be employed to dislodge the liquid adhering to the particles and because of capillary forces. between the particles Furthermore, low pressure drying steps (such as with spray dryers or cryogenic drying) with or without convective qas flow may be employed between the wash steps to assist removal of the interface liquid. It is preferred if the extent of washing needed is monitored on-line suitable instrument such as a pH meter.

In one embodiment, the washed precipitate is calcined а temperature sufficient to convert at in In another embodiment, the hydroxide into an oxide. is changed to oxygen calcination environment environment or to hydrogen rich environment or to carbon nitrogen rich environment environment or to produce stoichiometric oxides, non-stoichiometric oxides and nitrides (reduced oxide) or metals, carbides respectively.

The calcination temperature is preferably determined precipitate processed follows-the is with analyzer in line thermogravimetric spectrometer (TGA-MS) where the weight loss as a function of temperature is monitored along with the composition of the species formed during the said weight loss. The the highest preferred calcination temperature is temperature above which (a) the rate of weight loss is always less than 5%, preferably 1% and most preferably 0.1%; and (b) the change of composition for any species is always less than 5%, preferably 1% and most preferably of multiple temperatures, the 0.1%. In case The calcination temperature is temperature is preferred.

15

20

25

30

preferably less than 0.5 times the melting point of the precipitate or the final product. While these guidelines are useful for many applications, the guidelines should be relaxed whenever the product formed at a lower temperature meets the needs of the desired user application. Finally, it should be noted that the guidelines may also be relaxed to reduce energy costs.

The calcination temperature may be reached using various temperature ramping methods. It is preferred to use an optimum ramp that reduces energy cost and processing time while maximizing the product quality. The heating environment may be changed during the ramp cycle to tailor the properties of the powders produced.

The calcination step may be carried out in any equipment. Some non-limiting illustrations include rotary kiln, fluidized bed, co-current or counter current spray reactor, spouted reactor, tray type reactor, pneumatic conveyor with recycle, thermal processors, and furnace. The calcination may also be done using microwave ovens and furnaces for rapid heating cycles.

In another embodiment, the washed precipitate organometallic solution before the with washed an calcination step elaborated above. For example, one may utilize the organometallic precursor solution resulting from the process outlined in Figure 1. Alternatively, commercially available organometallics such as titanates and zirconates (e.g. TYZOR®), alkoxides, chelates, alkyls, metallocenes, and other compositions may be utilized. preferred organometallic is one that (a) reacts with the precipitate's surface hydroxide functional group and forms a monolayer on the surface; (b) the presence of surface layer of another metal enhances the powder's performance

10

15

20

25

30

or at least does not adversely affect the performance of the powder; (c) reduces formation of hard agglomerates during calcination; and (d) is affordable. If desired, the precipitate after organometallic solution treatment may be filtered, washed and/or dried before calcination.

As a non-limiting example, 1 ml $TYZOR^{\otimes}$ TOT^{\otimes} (from $DuPont^{\otimes}$) in 100 ml isopropanol is a specific illustration of an organometallic solution for wash purposes.

In yet another embodiment, dopants preferably nanodopants or other precipitate powders are added to the filtered and washed precipitate before the calcination step. It is preferred if the powders are well mixed using mechanical or other means.

This invention can also be utilized to produce pure In this case, the dissolved solution or the powders. precipitate obtained and shown in Figure 2 is purified using one of the many techniques known for purification of liquids and solids. Some non-limiting illustrations electrochemical purification, sequential include purification, crystallization methods, extraction distillation purification, chromatographic purification, membrane purification, and sublimation purification.

The calcination step yields the desired nanopowders. The calciner may be heated electrically or with natural gas or other available heat sources. In a preferred embodiment, the calcined powders are homogenized, sieved, and/or blended in-situ or post-calcination to ensure acceptability and uniform quality of the powders for a given application. If desired, a dispersion such as ink or paste may be made inside the calcination reactor by adding appropriate solvents and dispersants. The

10

15

20

25

30

nanopowders can be removed from the calcination equipment using a number of methods. Some non-limiting examples include pneumatic conveying, screw conveying, venturi type eductor remover, or pumping. In case the nanopowders are removed using a gas conveying method, the powders can be removed near a packaging unit with a high efficiency membrane containing filter or cyclone.

The packaging of the nanoscale powders into suitable may be done using auger filler based packaging system or any powder packaging equipment. The packaging environment may be an inert or air. The packaging container may be made of an multilaminate or single layer, metallic or glass or plastic, rigid or flexible, insoluble or soluble material for ease of handling in ultimate application. Adequate labels and stamping may be done on the packaging safety, for handling instructions, material information, re-ordering information, laser or radio chip logistics, and may include any desired markers for marketing and other information. It is preferred if the packaging unit allows ease of use while maximizing safety and exposure prevention.

A coating, film, or component may also be prepared by dispersing the fine nanopowder and then applying various known methods such as but not limiting to electrophoretic deposition, magnetophorectic deposition, spin coating, dip coating, spraying, brushing, screen printing, ink-jet printing, toner printing, and sintering. The nanopowders may be thermally treated or reacted to enhance its electrical, optical, photonic, catalytic, thermal, magnetic, structural, electronic, emission, processing or forming properties before such a step.

10

15

20

25

It should be noted that the intermediate or product at any stage in Figure 2, or similar process based on modifications by those skilled in the art, may be used directly as feed precursor to produce nanoscale or fine powders by methods such as but not limiting to those taught in commonly owned U.S. patents 5788738, 5851507, 5984997, and co-pending applications 09/638,977 and 60/310,967. For example, a sol may be blended with a fuel and then utilized as the feed precursor mixture for thermal processing above 2500K to produce nanoscale simple or complex powders.

Example 1: Yttrium Oxide Powders

 $Y(NO_3)_3 - 6H_2O$ [5.9 g] was weighed and dissolved in demineralized water. Total volume of solution was 150 ml. To precipitate Y(OH)3, NH4OH was used as precipitating agent. NH4OH was diluted in demineralized water (20 ml in 200 ml of solution). 35 ml of NH4OH solution was added to the $Y(NO_3)_3$ solution slowly over 15 min. This raised the pH of the solution to 9.5. The precipitate was stirred for 20 min to ensure pH equilibrium. The precipitate was under vacuum and 200 washed with demineralized water twice. The powder was then calcined at 750 C by ramping the temperature rise at 10 C/min. calcination was done for 30 minutes. The nanopowder produced had an XRD crystallite size of 15-17 nm and a BET surface area of $72.5 \text{ m}^2/\text{gm}$. This example shows that oxide nanopowders can be produced.

Example 2: Yttrium Oxide Powders

 $Y(NO_3)_3 \bullet 6H_2O$ [5.9 g] was weighed and dissolved in demineralized water. Total volume of solution was 150 ml. To precipitate $Y(OH)_3$, NH_4OH was used as precipitating

15

20

25

30

agent. NH4OH was diluted in demineralized water (20 ml in 200 ml of solution). 35 ml of NH4OH solution was added to the Y(NO3)3 solution slowly over 15 min. This raised the pH of the solution to 9.5. The precipitate was stirred for 20 min to ensure pH equilibrium. The precipitate was washed with filtered under vacuum and 200 demineralized water twice. The powder was then calcined at 675 C by ramping the temperature rise at 10 C/min. calcination was done for 30 minutes. The nanopowder produced had an XRD crystallite size of 13-14 nm and a BET surface area of 81.3 m²/qm. This example shows that calcination temperature can be utilized to tailor the powder characteristics.

Example 3: Yttrium Oxide Powders

 $Y(NO_3)_3$ •6 H_2O [5.9 g] was weighed and dissolved in demineralized water. Total volume of solution was 150 ml. To precipitate Y(OH)3, NH4OH was used as precipitating agent. NH4OH was diluted in demineralized water (20 ml in 200 ml of solution). 35 ml of NH40H solution was added to the Y(NO3)3 solution slowly over 15 min. This raised the The precipitate was stirred pH of the solution to 9.5. for 20 min to ensure pH equilibrium. The precipitate was under vacuum and washed with 200 of filtered twice. After filtration the demineralized water precipitate was washed with an organometallic solution (1 ml Tyzor TOT diluted to 50 ml with anhydrous isopropanol). Then it was filtered again, dried in oven at 120°C and The powder was then calcined at 750 C by ramping ground. The calcination was the temperature rise at 10 C/min. done for 30 minutes. The nanopowder produced had an XRD crystallite size of 11 nm and a BET surface area of 99.7 m²/qm. This example shows that washing with organometallic way solution unusual to tailor the is an

10

15

25

30

characteristics even when high calcination temperature are used or necessary.

Example 4: Aluminum Oxide Powders

Aluminum isopropoxide was used as the raw material. It is affordable and easy reacts with nitric acid to produce soluble aluminum nitrate. In 1 L beaker 500 ml of demineralized water was added. To this, 100 ml (142 g) of HNO_3 was added and stirred for about 20 min. Next, 60 g of Al-isopropoxide (20 g at a time) was added to the nitric acid solution. Clear solution was formed in about 30 min. This solution was then used for further experiments.

200 ml Al(NO3)3 solution was diluted with 500 ml of demineralized water. For precipitating agent, 20 ml of concentrated NH4OH was added to 200 ml water solution. Under constant stirring, 220 ml of NH₄OH solution was added to 200 ml of aluminum nitrate solution drop by drop over 2 The solution was stirred additional 20 min to ensure pH equilibrium. The precipitate was filtered using filter was then rinsed with Buchner funnel. The deionized (DI) water twice. The precipitate was dried at 120 C for 12 hours. The surface area of the precipitate after drying was over 250 m²/gm with XRD grain size of 2 to The powder was next calcined at 550 C for 5 hours using a ramp of 10 C/min. The BET of the powder was still over 250 m²/qm. Calcining the powder to 950 C for 1 hour yielded delta alumina nanopowders with surface area of 128 m^2/qm .

Example 5: Aluminum Oxide Powders

The same procedure as in Example 4 was followed. The precipitate after the filtration step was collected into a beaker and washed with an organometallic solution (150ml

15

20

25

30

of IPA with 3 ml Tyzor TOT in it). The precipitate was dried at 120 °C and then ground. The powder was then calcined at 950 C for 1 hour (10 C/min ramp) yielded alpha alumina nanopowders with surface area of 89.0 m²/gm. Some titania was also detected during XRD. This example illustrates that the phase of alumina formed can be tailored using organometallic wash step. The example also illustrates the manufacture of titania doped alumina (which is useful in high voltage components).

10 Example 6: Ceria Powders

10 g of (NH_4) 2Ce (NO_3) 6 were dissolved in 400 ml of DI Then slowly, under constant stirring 25 ml of NH4OH solution (20 ml of conc. NH4OH in 200 ml of total solution) was added, until the solution reached pH 8.5-9. Purple-gray precipitate was formed. The suspension was about min. to equilibrate pH. The stirred for 20 precipitate was filtered using a Buchner funnel. filter-cake was rinsed with DI water twice. The "drylooking" filter cake was transferred into crucible and calcined at 900°C for 1 h, ramp - 10°C/min. The ceria powder formed had an XRD size of 64 nm and a surface area less than 1 m^2/g .

Example 7: Ceria Powders

15 g of Ce(NO₃)3x6H₂O were dissolved in 800 ml of DI water. Then the same precipitation procedure as in Example 6. The light purple precipitate was separated by letting it settle down and slowly decanting the water from the top as much as possible. Next the remaining suspension was filtered and rinsed with DI water. The precipitate was dried at 100-110°C for about 12 hours. The powder turned yellow. The powder was then ground. The powder was found to have a particle size of 10-12 nm (XRD) and was ceria.

15

20

25

30

BET surface area was 108 m²/g. In this case The However, thermal treatment calcination was not needed. was done using a TGA at 900°C for 1 h, ramp - 10°C/min to determine the thermal effect on the powder. The powder grew to a size of 38-67 nm per XRD and the surface area reduced to about 9 m^2/q . This example illustrates the importance of starting material and the fact calcination is sometimes not necessary.

Example 8: Ceria Powders

started with this experiment, we 20 1000 ml of DI water. Then the $Ce(NO_3)3x6H_2O$ in procedure as Example 6 was used. However, in this case the pH was brought to between 10-11 with addition of more precipitating agent and the precipitate powder was then treated with an organometallic solution. 100 ml organometallic solution (1 ml of Tyzor in about 100 ml of The powder was isopropanol) was added to the powder. stirred to produce a dispersion. The dispersion was filtered and dried at 100-110°C. The powder was then ground and analyzed. The XRD size was found to be 8-9 nm and the surface area was observed to be about 170 m²/gm. The powder was then calcined at 500 C for 1 hour (ramp of 10 C/min) to observe the stability of the nanopowder. powder was found to be about 8-14 nm after the thermal treatment and with the surface area of about 123 m²/gm. Further thermal treatment to 800 C was done and it was found that the ceria powder is still about 8-11 nm in This example illustrates that organometallic wash size. impact the mean particle size of significant can nanopowders and the thermal stability of nanopowder at temperatures as high as 800 C.

10

Example 9: Precursors and Powders

In production runs various types of feeds are used to produce nanoscale powders. The feed precursor mixtures were fed into a process described in US Patent 5,788,738 application 09/638,977 and co-pending patent 60/310,967. In these processes, the precursor mixture is fed into a thermal reactor under conditions that favor nucleation, then thermally quenched. The selected precursor mixtures described herein are substituted for the gas-suspended solid precursors described in Table 1 referenced patents and patent applications. outlines exemplary precursor mixtures used and the powder These precursor mixtures meet the product produced. requirements explained in detail earlier.

Table 1.

Feed Precursor Mixture	Viscosity	Average Approx. Mol Wt of each metal containing species per mol of metal atom in the species	Product
Zirconium Acetate + Water + Iso- propyl Alcohol	7-15 cP	164 gms / mol Zr	Zirconia
Zirconium HEX-CEM™	20-30 cP	506 gms / mol Zr	Zirconia
Zirconium HEX-CEM TM + Octamethyl- cycletetra- siloxane	2-10 cP	506 gms / mol Zr 74 gms / mol Si	Zirconium Silicates
AOC TM + Octamethyl- cycletetra- siloxane	24-35 CP	385 gms / mol Al 74 gms / mol Si	Aluminum Silicates
Barium Plastistab™ + AOC™ + Octamethyl- cycletetra- siloxane	20-30 CP	397 gms / mol Ba 385 gms / mol Al 74 gms / mol Si	Barium Aluminum Silicates
Yttrium 2-EH + Zirconium HEX-CEM TM	25-40 cP	506 gms / mol Zr 1893 gms / mol Y	Yttria Stabilized Zirconia
Zn HEX-CEM™ + Naphtha	Less than 100 cP	361 gms / mol Zn	Zinc Oxide
Cerium HEX- CEM [™] + Naphtha	Less than 100 cP	350 gms / mol Ce	Cerium Oxide

Uses

5

Once the precursor is available, they may be used in any number of applications including the production of nanopowders by methods such as, but not limited to, methods taught in the US Patent 5,788,738 (which and its references are herewith included by reference in full). Other applications of the precursors include coatings, surface treatment, catalysis, reagent, precursors, tracers

Catalytic materials that are prepared from purer powders can last longer and give Magnetic devices prepared from superior selectivity. expected to offer powders are superior purer fine Nanoscale powder based composites magnetic performance.

are expected to be more corrosion resistant. In general, nanoscale powders offer a means of improving the value-added performance of existing products that are produced from less pure powders.

Table 2 outlines exemplary applications of fine powders produced by techniques described in this invention.

TABLE 2.

5

Application	Ceramic Nanopowder Composition
ELECTRICAL DEVICES: Capacitors, Resistors, Inductors, Integrated Passive Components	Barium titanate, strontium titanate, barium strontium titanates, silicates, yttria, zirconates, nanodopants, fluxes, electrode formulations
ELECTRONIC PRODUCTS: Substrates, Packaging	Alumina, aluminum nitride, silicon carbide, gallium nitrides, cordierite, boron carbide, composites
PIEZO DEVICES: Piezoelectric transducers	PZT, barium titanate, lithium titanates, nanodopants
MAGNETIC DEVICES: Magnets	Ferrites, high temperature superconductors
Electroptics	(Pb,La)(Zr,Ti)O3, nanodopants
Insulators	Alumina
CIRCUIT PROTECTION DEVICES: Varistors	ZnO, titania, titanates, nanodopants
SENSING DEVICES: Thermistors	Barium titanates, mangnates, nanodopants
ENERGY DEVICES: Fuel Cells, Batteries, Electrolytic Capacitors	Zirconia, ceria, stabilized zirconia, interconnects materials, electrodes, bismuth oxide, nanodopants, lithium cobalt oxide, lithium manganese oxide, manganese oxide, nickel metal hydrides, zinc oxide, carbides, nitrides
Mechanical components	Silicon nitride, zirconia, titanium carbide, titanium nitride, titanium carbonitride, boron carbide, boron nitride
HEALTH CARE PRODUCTS: Biomedical Devices,	Aluminum silicates, alumina, hydroxyapatite, zirconia, zinc oxide, copper oxide, titania, polymer
District Devices,	copper oxide, citalita, porfiler

15

Implants, Surgical tools, Tracer, Marker, Drug Delivery, Topical creams	composites, alloys, agglomerated powders
COATINGS	Indium tin oxide, nanostructured non- stoichiometric oxides, titania, titanates, silicates, chalcogenides, zirconates, tungsten oxide, doped oxides, concentric coated oxides, copper oxide, magnesium zirconates, chromates, oxynitrides, nitrides, carbides, cobalt doped titania
Colors and Pigments	Oxynitrides, titanias, zinc oxides, zirconium silicates, zirconia, doped oxides, iron oxides, strontium aluminates, rare earth oxides, phosphors
Catalysts	Aluminum silicates, alumina, mixed metal oxides, zirconia, metal doped oxides, zeolites
Abrasives, Polishing Media	Aluminum silicates, alumina, ceria, zirconia, copper oxide, tin oxide, zinc oxide, multimetal oxides, silicon carbide, boron carbide

Fig. 3 shows a schematic flow diagram of a process for the continuous synthesis of precursors and nanoscale powders in accordance with the present invention. The continuous synthesis processes of Fig. 3 are analogous to the general processes described with respect to Fig. 1 and Fig. 2, but are advantageous in that the tend to provide volume, scaleable, mass production high The continuous synthesis process of Fig. 3 techniques. enables a wide variety of raw materials to be processed Because the precursor solution or into fine powders. mixture that feeds the ultimate nanoscale powder process is synthesized inline, the precursor mixtures can have a much wider range of shelf life or stability that is possible when the precursor mixture is produced in advance of the synthesis process. This, in turn, increases the variety of precursor mixtures that are available with a corresponding increase in the variety of powders that can be produced.

15

20

25

30

Moreover, the continuous synthesis process of Fig. 3 often lowers the cost of producing powders as compared to processes that obtain precursors and precursor mixtures separately from the fine powder synthesis process. The control over physical and chemical properties of the precursor mixture such as composition, molecular weight, viscosity, melting point and uniformity are greatly improved.

The embodiment of Fig. 3 is intended as an example to demonstrate a particular system for continuous synthesis of fine powders from raw materials. It should be understood that a wide variety of alternatives exist for most process steps, and in many implementations process steps may be eliminated or additional process steps integrated to meet the needs of a particular application. These variations are within the scope of the present invention.

In addition to the raw material supply 301, various process chemicals such as DI water, Nitric acid, ammonium hydroxide, 2 ethylhexanoate (2-EH), and Naptha are provided. These process chemicals are coupled by metered pumps 302 to reactor 303. Preferably, temperature and pH monitors are included inline with each component. Any number of valves may be included in the system to provide additional control, safety, and/or other purposes.

Reactor 303 is preferably heated by a heater jacket or other means to control the reaction temperature. The reaction is preferably monitored by temperature and pH monitors. The output of reactor 303 is monitored for viscosity, concentration, or other parameters of interest in a particular implementation. To the extent practical, separator 304 is used to separate water, solvents, acids,

10

15

20

25

or other materials. Separator 304 outputs a product to filter 305 which may be implemented as a centrifugal filter with a solid scraper in a particular example. DI water is provided to rinse the reactor product.

The product of filter 305 may be further processed by a solid digestor 306 which may be fitted with a jacketed heater. Optionally, a slurry eductor 307 is used to ease and immprove flow of the product of filter 305. 2-EH may be provided to digestor 306 to react the hydroxide functional group and produces an organometallic output 7. The organometallic output from digestor 306 is further processed by a viscosity controller tank 308 to provide useful form of precursor mixture.

Alternatively, the output of filter 305 may provided inline to flash calcinator 309 heated by a gas heater 310, or equivalent heating source. mechanism example of calcinator 309 is one а performing the thermal treatment step shown in Fig. flash calcinator 309 is supplied to a The output of powder/qas filter 311 for collection of fine powders, including sub-micron and nanoscale powders.

Other embodiments of the invention will be apparent to those skilled in the art from a consideration of the specification or practice of the invention disclosed herein. It is intended that the specification and examples be considered as exemplary only, with the true scope and spirit of the invention being indicated by the following claims.
